*The Spectral Monk*

The celebrated tavern of the Pomme d'Ève was situated in the University, where the Rue de la Rondelle met the Rue du Bâtonnier. It was a vast ground-floor room, with a very low, vaulted ceiling whose central springing rested on a huge wooden pillar painted yellow; tables everywhere, gleaming pewter hanging from the wall, never any shortage of customers, girls by the score, a glass front on to the street, a vine by the door, and above this door a gaudy metal plate, decorated with a woman and an apple, which had gone rusty in the rain and swung in the wind on an iron hinge-pin. This sort of weathercock overhanging the pavement was the inn-sign.

Night was falling. The crossroads was in darkness. From a distance, the tavern full of candles blazed in the shadows like a forge. Through the broken window-panes came the sound of glasses, of carousing, of swearing and quarrelling. Through the mist formed by the heat of the room on the glass front, dozens of blurred figures could be seen milling about, from whom there now and again came a resounding shout of laughter. The passers-by did not look in through those turbulent window-panes as they went about their business. Except, from time to time, when some small ragamuffin stretched up on tiptoe to the window-rail and hurled into the tavern the mocking old cry with which drunkards were then pursued:

'Halloo, halloo, you're boozy.'

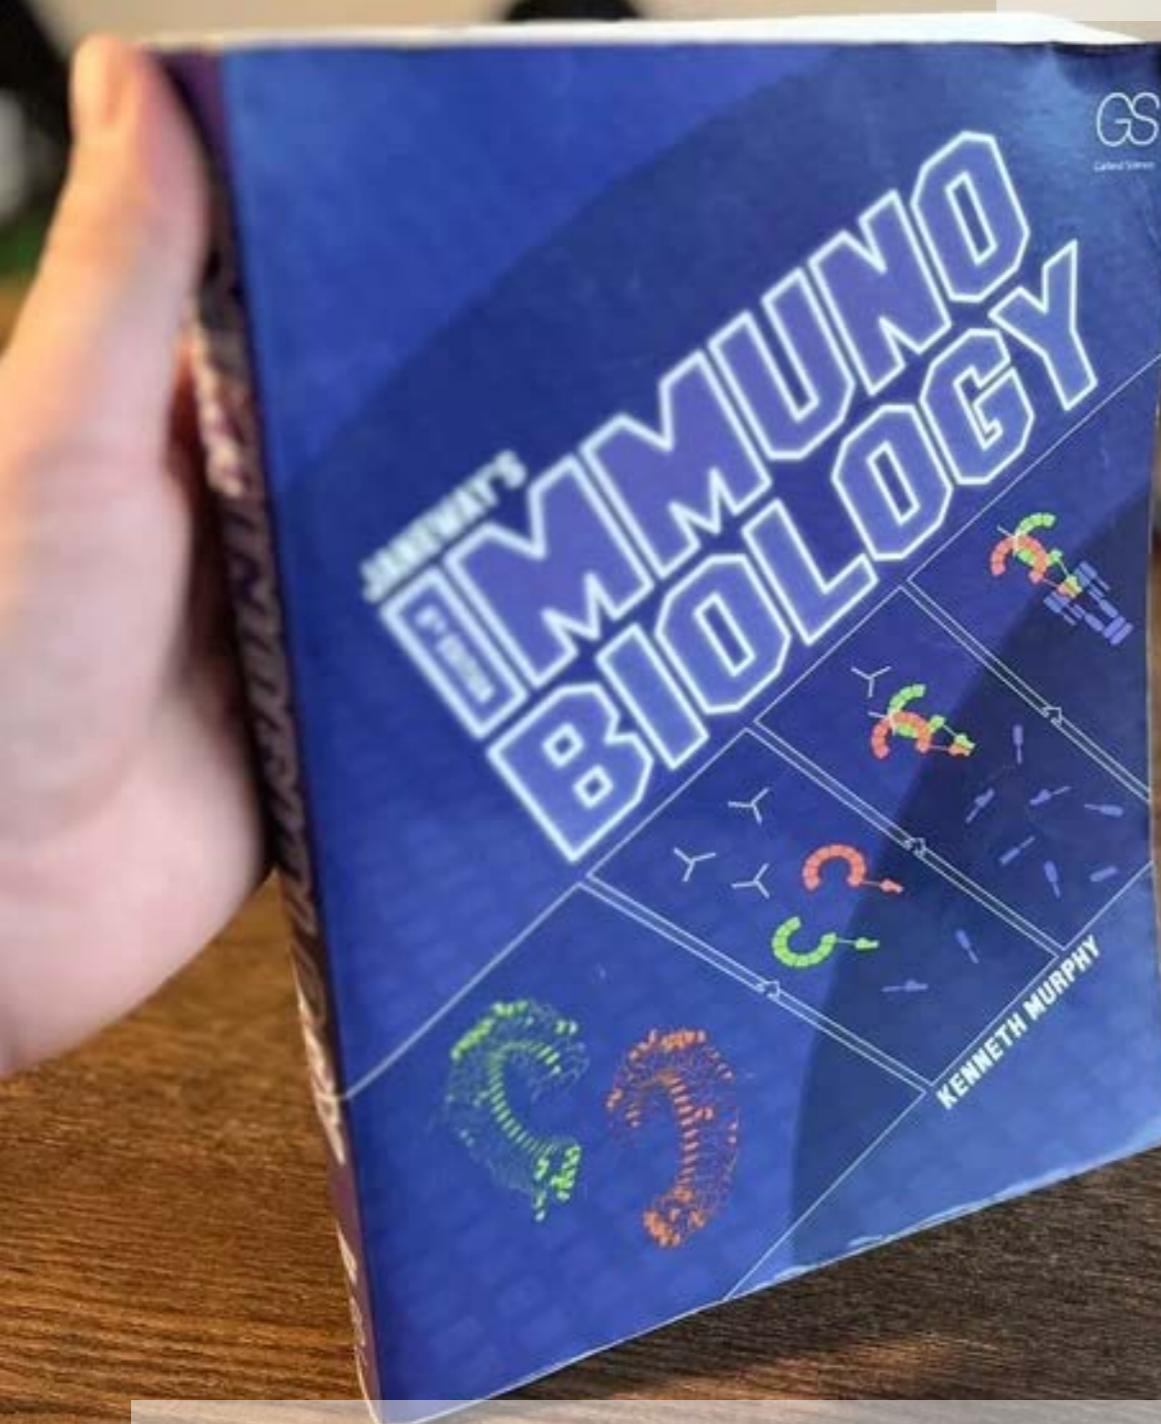

Yet one man walked imperturbably to and fro past the rowdy tavern, who looked in constantly and strayed no further from it than a pikeman from his sentry-box. A cloak was pulled up round his eyes. This cloak he had just purchased from the old man next door to the Pomme d'Ève, no doubt to conceal his face from the chill of a March evening, or perhaps to conceal his figure from the eyes of the watermen.

From time to time, he stopped in front of the window with its lead lattice-work, to listen, to look, to shake his head, to scratch his feet.

The tavern finally opened. This was what he

Kenneth Murphy—Janeway's Immunobiology  
(8th Edition)

It is remarkable to delineate these cells as memory CD4 T cells that naive CD4 T cells differentiate into effector T cells, some of these memory cells. As with memory CD8 T cells, direct staining with peptide-MHC class II tetramers can identify antigen-specific cells, and analysis using intracellular cytokine staining (see section A-27) can determine whether they are T<sub>H</sub>1, T<sub>H</sub>17, or T<sub>H</sub>2. Improvements in the identification and phenotyping of CD4 T cells will increase our knowledge in this area and could contribute valuable information on naïve, memory, and effector CD4 T cells.

mechanisms governing the survival of memory T cells are similar to those for naïve T cells. Memory T cells divide more frequently than naïve T cells, and their expansion is controlled by a balance between cell division and cell death. As with naïve cells, the survival of memory T cells is dependent on cytokines. IL-2 and IL-15; IL-2 is required for the survival of CD4 and CD8 memory T cells, but in addition, IL-15 is critical for the survival and proliferation of CD8 memory T cells under certain conditions. For memory CD4 T cells, the role of IL-15 is still under investigation.

Naive T cells require signals from contact with self-peptide-self-MHC complexes and the cytokines IL-12 and IL-7 for survival.

Naive T cell encounters antigen.

Naive T cells are heterogeneous and include central memory and effector memory subsets.

T cells can differentiate into two types of memory cells with distinct characteristics (Fig. 11.25). One type is called an effector because it can rapidly mature into an effector T cell and secrete IL-2, IL-4, and IL-5 early after restimulation. These cells lack the receptor CCR7 but express high levels of  $\beta_1$  and  $\beta_2$  integrins and receptors for inflammatory chemokines. This profile suggests that memory cells are specialized for rapidly entering inflamed tissue. The other type is called a central memory cell. It expresses CCR7 and can be expected to recirculate more easily to the T-cell zones of lymphoid tissues, as do naïve T cells. Central memory cells are very long-lived, as evidenced by the slow rate of self-peptide-self-MHC complexes for their long-term survival. However, this generalization does not apply to all memory cells. Some activated effector cells become long-lived memory cells.

Many effector cells are short lived and die by apoptosis.

Cytokines IL-7 and IL-15 are required for survival.

Memory T cells need contact with self-peptide-self-MHC complexes to continue to proliferate.
